Likes say far more about views than the follower count

How far off are we?

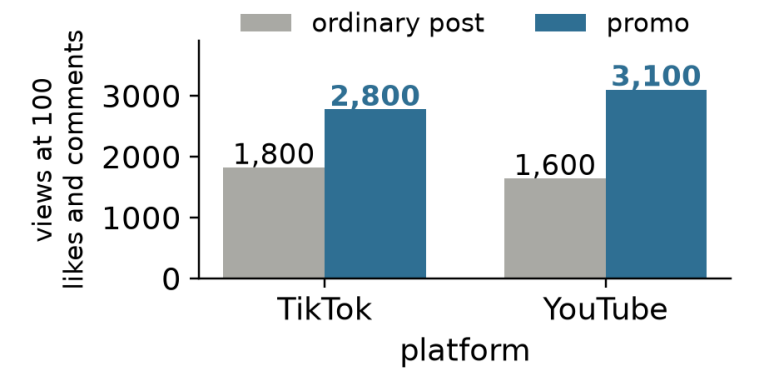

Constant × followers: ×7-8. Model with reactions: ×2-3. On X Brand24 about ×12, ours about ×3.

What matters most?

Likes alone go furthest. The type of post says almost nothing.

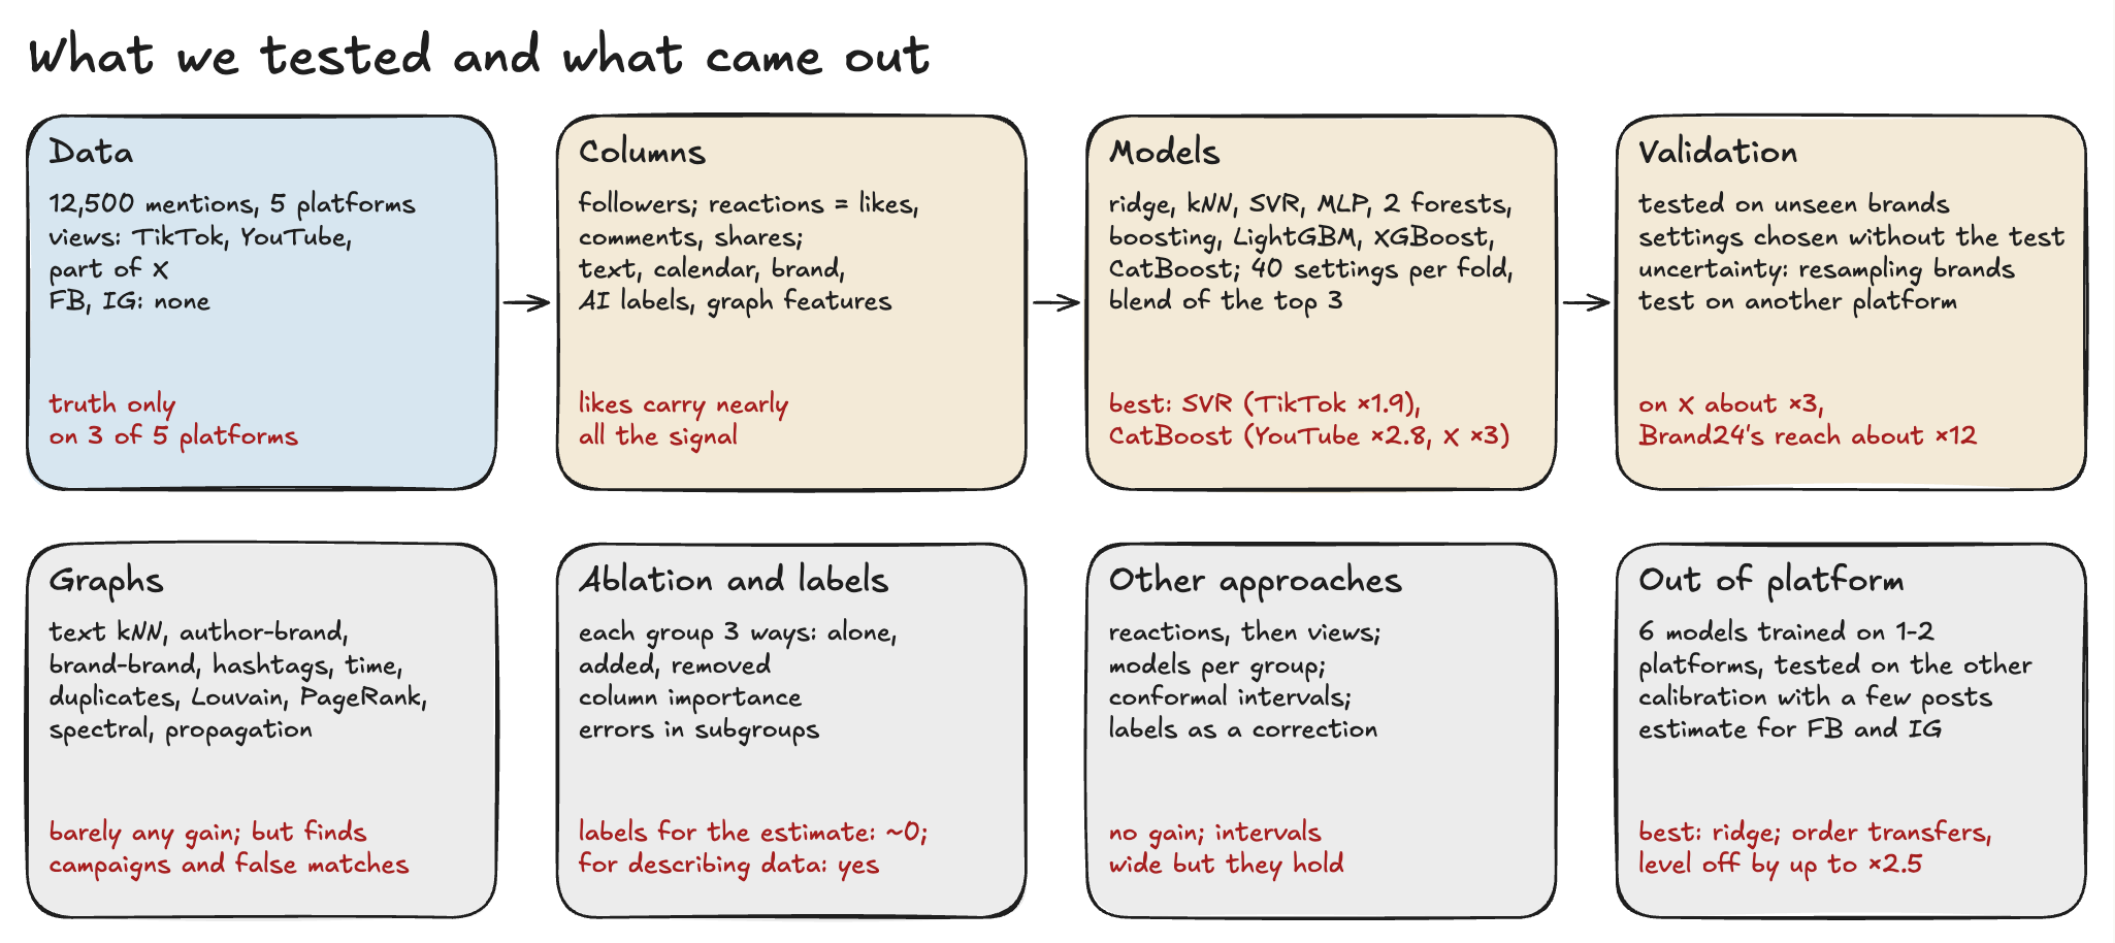

Does the kind of post help?

AI labels barely help the estimate, but promo gets 1.5-1.9× the views.

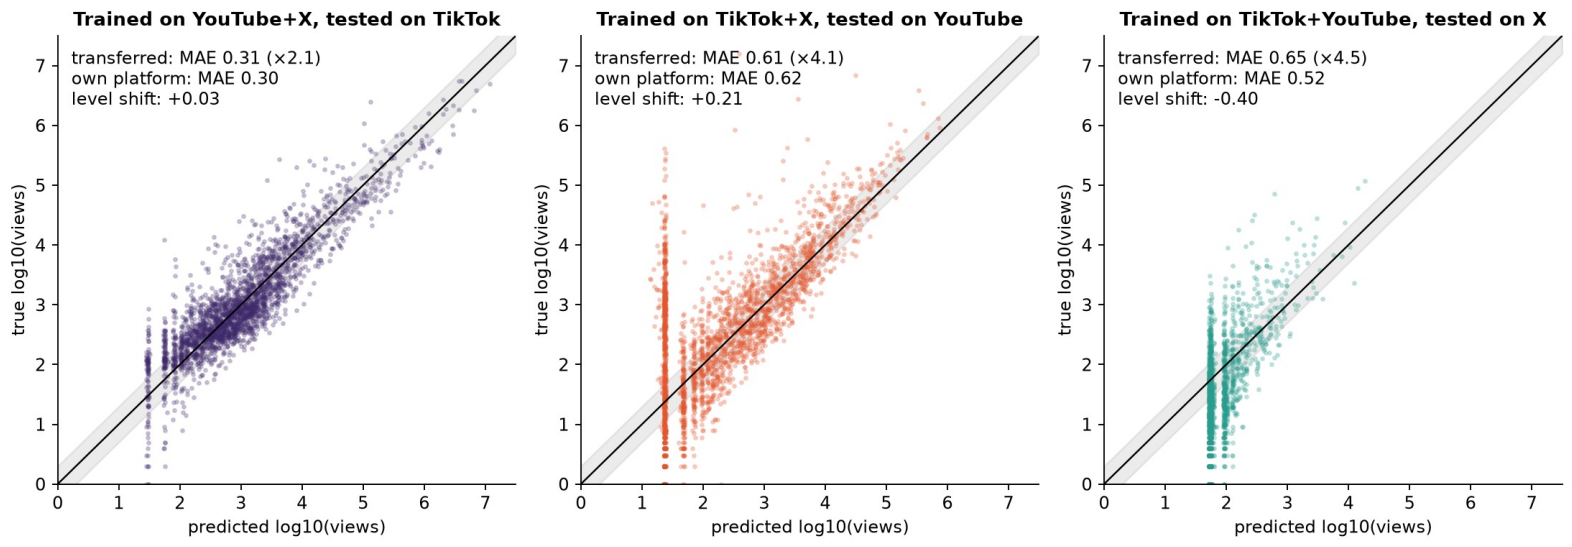

"Off by ×3" = typically 3 times too high or too low. Reactions = likes, comments, shares. Tested on brands the model has not seen.

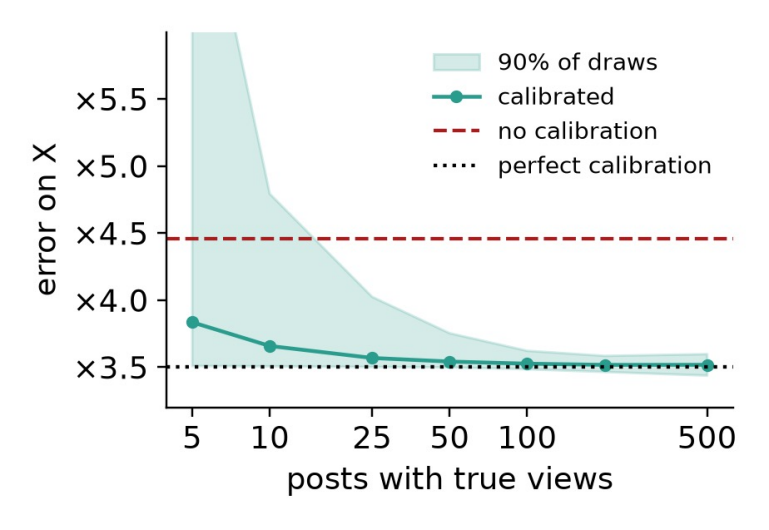

We tested 10 kinds of model: the best are off 2-3 times, and extra data and graphs barely change that

Best: SVR (TikTok), CatBoost (YouTube, X). 40 settings per model.

A model from another platform ranks posts well but can miss the scale; about 50 posts fix that

Another platform

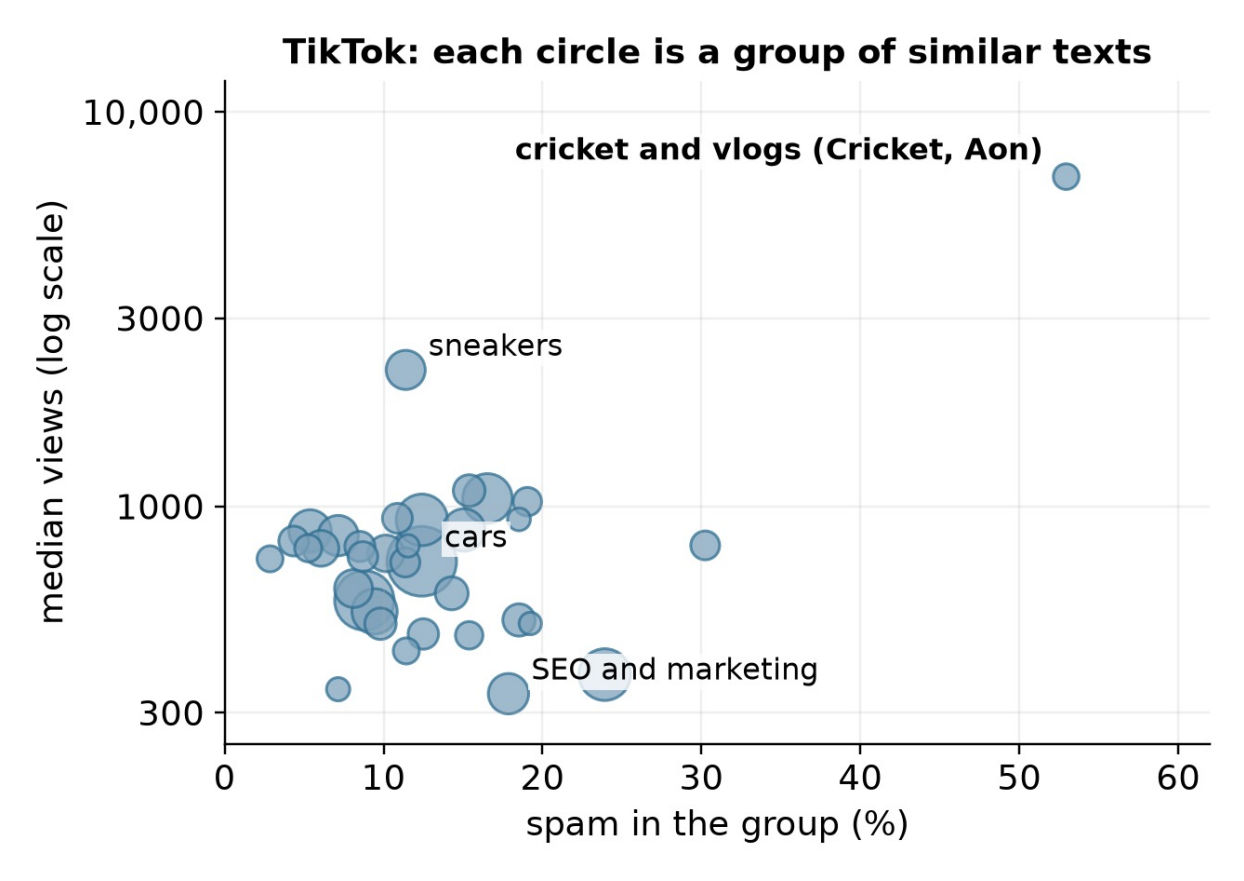

TikTok ×2.1, YouTube ×4.1: nearly as on own data. X: ×4.5 instead of ×3.3, as everything is about 2.5× too high.

A small sample is enough

50 posts from X: error ×4.5 → ×3.5. FB and IG need such a sample.

Ridge trained on two platforms, tested on the third. Calibration tested only where the truth is known.

Graphs barely improve the estimate, but they show what is really in the data

For the estimate: 18 variants, at most +0.009.

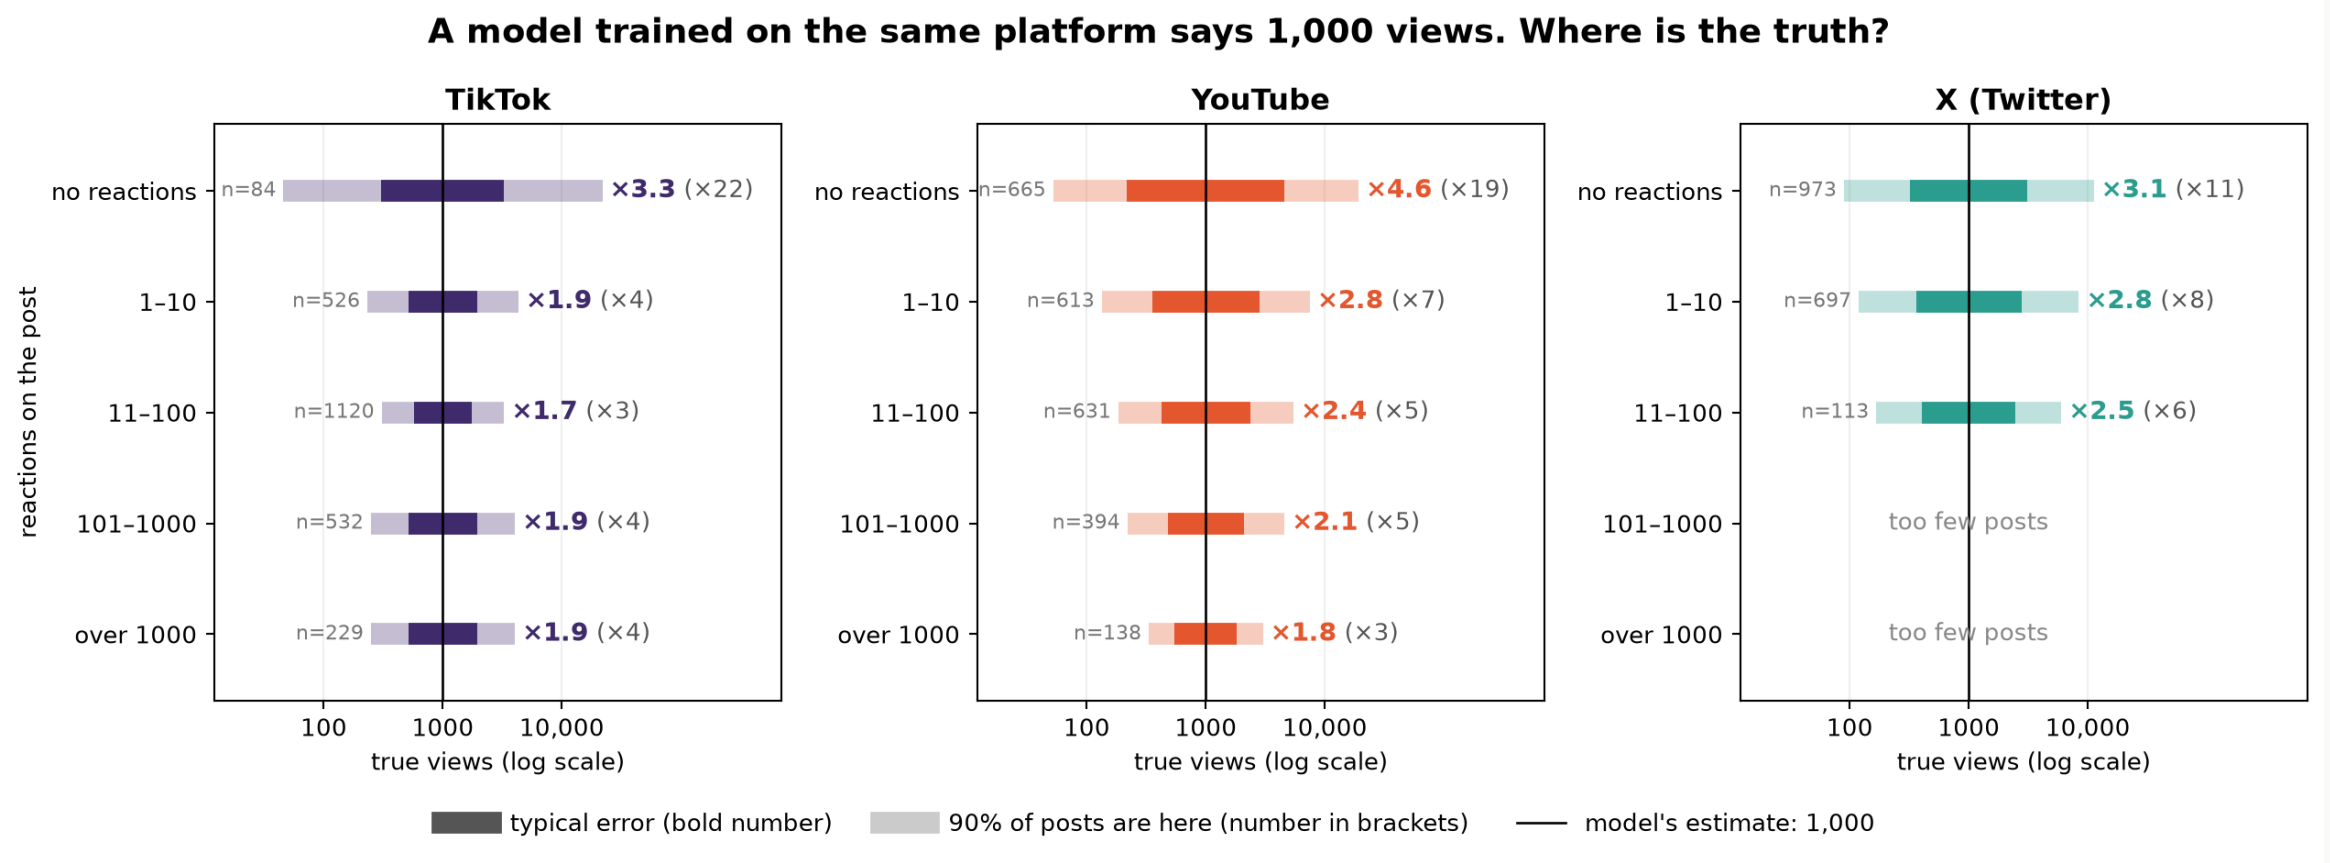

For describing the data: industries emerge; 38% of duplicates on X are spam (rest 9%).

A curiosity: "Cricket Wireless" on TikTok is the sport: 0 of 20 posts about the company.

Each post links to its 10 most similar texts; Louvain splits the graph into groups by itself.

BACKUP · UNCERTAINTY

Without reactions the estimate is uncertain; with reactions the range narrows sharply

CatBoost trained on the same platform. Dark bar: typical error; light: 90% of posts.
